

Recoverable Money with Sixth-Degree Harmonic Feedback

Soumadeep Ghosh

Kolkata, India

Abstract

This paper develops a mathematical theory of recoverable money. The central object is a monetary process $M(t)$ that departs from an initial level, undergoes nontrivial dynamics, and subsequently returns to its initial value at a finite recovery horizon. A complete characterization of all degree-eight recoverable monetary trajectories is obtained. The resulting representation naturally generates a sixth-degree feedback kernel. Particular attention is devoted to harmonic feedback, wherein the kernel coefficients form a harmonic progression.

The framework admits interpretations in economics, finance, political economy, international relations, warfare economics, control theory, statistics, computer science, and machine learning. The resulting system combines finite-horizon recoverability, historical memory, nonlinear feedback, and diminishing higher-order influence within a unified analytical structure.

The paper ends with “The End”

1 Introduction

Many dynamic systems exhibit temporary excursions followed by eventual recovery.
Examples include:

- monetary expansions followed by normalization,
- sovereign reserve accumulation and drawdown,
- wartime mobilization followed by demobilization,
- strategic investment cycles,
- liquidity injections followed by withdrawal,

- technological investment waves,
- reinforcement-learning systems with bounded state recovery.

Such systems possess two apparently contradictory properties:

1. path dependence,
2. eventual return.

The objective of this paper is to formalize this combination mathematically. We introduce a class of monetary trajectories satisfying

$$M(0) = M(T) = m,$$

while maintaining rich intermediate dynamics.

The resulting framework leads naturally to a sixth-degree feedback kernel and a harmonic feedback specification possessing attractive analytical properties.

2 The Fundamental Monetary Identity

Let

$$M(t)$$

denote a stock of money, wealth, reserves, liquidity, or financial resources. Consider the identity

$$M(t) = M(t) - \lambda(t) \frac{dM(t)}{dt} + \mu(t) \int_0^t M(s) ds.$$

Subtracting $M(t)$ from both sides yields

$$\lambda(t) \frac{dM(t)}{dt} = \mu(t) \int_0^t M(s) ds.$$

Define the historical monetary memory

$$H(t) = \int_0^t M(s) ds.$$

The identity becomes

$$\lambda(t) \dot{M}(t) = \mu(t) H(t).$$

2.1 Interpretation

The equation balances:

- instantaneous monetary change,
- accumulated monetary history.

The coefficient $\lambda(t)$ weights present monetary flow, whereas $\mu(t)$ weights the contribution of accumulated monetary memory.

3 Recoverable Money

Definition 1 (Recoverable Money). *A monetary process is said to be recoverable over horizon T if*

$$M(0) = m$$

and

$$M(T) = m.$$

Recoverability does not imply triviality.

The process may experience substantial intermediate fluctuations while still satisfying endpoint recovery.

3.1 A Simple Example

Consider

$$M(t) = m + t^8 - T^7 t.$$

Then

$$M(0) = m$$

and

$$M(T) = m + T^8 - T^8 = m.$$

This provides a nontrivial degree-eight recoverable monetary trajectory.

4 Characterization of Degree-Eight Recoverability

The preceding example is merely one member of a much larger class.

The following theorem completely characterizes all such trajectories.

Theorem 1 (Recoverable Degree-Eight Money). *Let $M(t)$ be a polynomial of degree eight. Then*

$$M(0) = M(T) = m$$

if and only if there exists a unique degree-six polynomial $Q_6(t)$ such that

$$M(t) = m + t(t - T)Q_6(t).$$

Proof. Suppose

$$M(0) = M(T) = m.$$

Then

$$M(t) - m$$

has roots 0 and T .

By the Factor Theorem,

$$M(t) - m = t(t - T)R(t)$$

for some polynomial $R(t)$.

Since

$$\deg(M) = 8,$$

it follows that

$$\deg(R) = 6.$$

Defining

$$Q_6(t) = R(t)$$

gives

$$M(t) = m + t(t - T)Q_6(t).$$

Conversely,

$$M(t) = m + t(t - T)Q_6(t)$$

immediately implies

$$M(0) = m$$

and

$$M(T) = m.$$

Uniqueness follows from uniqueness of polynomial factorization. □

5 The Sixth-Degree Feedback Kernel

The most general sixth-degree polynomial is

$$Q_6(t) = a_6t^6 + a_5t^5 + a_4t^4 + a_3t^3 + a_2t^2 + a_1t + a_0,$$

where

$$a_6 \neq 0.$$

Substituting into the recoverability representation yields

$$M(t) = m + t(t - T)(a_6t^6 + a_5t^5 + a_4t^4 + a_3t^3 + a_2t^2 + a_1t + a_0).$$

5.1 Expanded Form

Expanding gives

$$\begin{aligned} M(t) = & m + a_6t^8 + (a_5 - Ta_6)t^7 \\ & + (a_4 - Ta_5)t^6 + (a_3 - Ta_4)t^5 \\ & + (a_2 - Ta_3)t^4 + (a_1 - Ta_2)t^3 \\ & + (a_0 - Ta_1)t^2 - Ta_0t. \end{aligned}$$

This expression spans the entire space of degree-eight recoverable monetary trajectories.

6 Harmonic Feedback

We now impose additional structure on the feedback kernel.

Definition 2 (Harmonic Feedback). *The kernel possesses harmonic feedback if*

$$a_0, a_1, \dots, a_6$$

form a harmonic progression.

Equivalently,

$$\frac{1}{a_k} = \frac{1}{a_0} + kd, \quad k = 0, \dots, 6.$$

Here d denotes the common difference of the reciprocal arithmetic progression.

Theorem 2 (Harmonic Feedback Kernel). *Suppose*

$$1 + ka_0d \neq 0, \quad k = 0, \dots, 6.$$

Then

$$a_k = \frac{a_0}{1 + ka_0d}.$$

Consequently,

$$Q_6(t) = a_0 \sum_{k=0}^6 \frac{t^k}{1 + ka_0d}.$$

Proof. From the harmonic progression assumption,

$$\frac{1}{a_k} = \frac{1}{a_0} + kd.$$

Taking reciprocals yields

$$a_k = \frac{1}{\frac{1}{a_0} + kd} = \frac{a_0}{1 + ka_0d}.$$

Substituting into

$$Q_6(t) = \sum_{k=0}^6 a_k t^k$$

gives

$$Q_6(t) = a_0 \sum_{k=0}^6 \frac{t^k}{1 + ka_0d}.$$

□

The resulting monetary trajectory becomes

$$M(t) = m + a_0 t(t - T) \left(\sum_{k=0}^6 \frac{t^k}{1 + ka_0d} \right).$$

7 Special Cases

7.1 Uniform Feedback

When

$$d = 0,$$

all coefficients coincide.

Thus

$$a_0 = a_1 = \cdots = a_6.$$

The feedback kernel becomes

$$Q_6(t) = a_0(1 + t + t^2 + t^3 + t^4 + t^5 + t^6).$$

Using the geometric-series formula,

$$Q_6(t) = a_0 \frac{t^7 - 1}{t - 1}.$$

7.2 Logarithmic Feedback

Suppose

$$a_0d = 1.$$

Then

$$a_k = \frac{a_0}{k + 1}.$$

Therefore

$$Q_6(t) = a_0 \left(1 + \frac{t}{2} + \frac{t^2}{3} + \frac{t^3}{4} + \frac{t^4}{5} + \frac{t^5}{6} + \frac{t^6}{7} \right).$$

Observe that

$$-\frac{\ln(1 - t)}{t} = \sum_{k=0}^{\infty} \frac{t^k}{k + 1}.$$

Hence the harmonic kernel becomes the sixth-order truncation of a logarithmic generating function.

8 A Geometric Representation

Figure 1 illustrates a generic recoverable monetary trajectory.

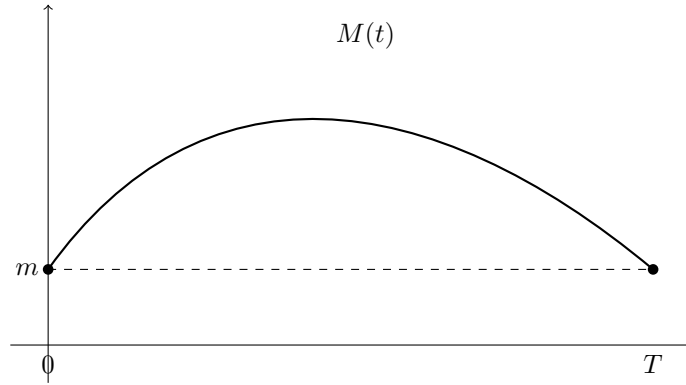

Figure 1: Recoverable money: nontrivial intermediate dynamics with endpoint recovery.

9 Dynamical Systems Interpretation

The recoverable-money framework admits a natural dynamical interpretation.

Define the memory state

$$H(t) = \int_0^t M(s) ds.$$

Then

$$\dot{H}(t) = M(t).$$

The fundamental monetary identity

$$\lambda(t) \dot{M}(t) = \mu(t) H(t)$$

may therefore be rewritten as

$$\dot{M}(t) = \frac{\mu(t)}{\lambda(t)} H(t).$$

Combining both equations yields the state-space system

$$\begin{pmatrix} \dot{M}(t) & \dot{H}(t) \end{pmatrix} = \begin{pmatrix} 0 & \frac{\mu(t)}{\lambda(t)} & 1 & 0 \end{pmatrix} \begin{pmatrix} M(t) & H(t) \end{pmatrix}.$$

9.1 Constant-Coefficient Approximation

Suppose

$$\frac{\mu(t)}{\lambda(t)} = \kappa,$$

where κ is constant.

Then

$$\dot{M} = \kappa H,$$

and

$$\dot{H} = M.$$

Differentiating once more gives

$$\ddot{H} = \kappa H.$$

Likewise,

$$\ddot{M} = \kappa M.$$

Proposition 1. *If $\kappa > 0$, the system exhibits exponential amplification.*

If $\kappa < 0$, the system exhibits oscillatory behavior.

Proof. The characteristic equation is

$$r^2 - \kappa = 0.$$

Hence

$$r = \pm\sqrt{\kappa}.$$

If $\kappa > 0$, the roots are real.

If $\kappa < 0$, the roots are imaginary. □

The recoverability constraint

$$M(0) = M(T)$$

may therefore be interpreted as a finite-horizon boundary condition imposed upon an otherwise dynamical system.

10 Monetary Memory

The variable

$$H(t) = \int_0^t M(s)ds$$

plays a central role throughout the theory.

Unlike a conventional stock variable, $H(t)$ records cumulative historical monetary exposure.

Examples include:

- cumulative liquidity provision,
- aggregate wealth-years,
- cumulative fiscal support,
- total reserve deployment,
- accumulated strategic expenditure.

Consequently, the model distinguishes between

$$M(t)$$

and

$$H(t).$$

The first measures present resources.

The second measures historical commitment.

11 Economic Interpretation

11.1 Money as a Recoverable State Variable

Traditional monetary models often focus on equilibrium levels.

The present framework instead studies complete trajectories.

A recoverable monetary process satisfies

$$M(0) = M(T),$$

yet generally

$$M(t) \neq M(0)$$

for

$$0 < t < T.$$

This permits temporary expansions and contractions.
Examples include:

- central-bank liquidity programs,
- emergency lending facilities,
- cyclical reserve accumulation,
- quantitative easing and reversal.

11.2 Monetary Inertia

The coefficient

$$\lambda(t)$$

measures resistance to monetary adjustment.

Large values imply that substantial historical pressure is required to alter current monetary growth.
Small values imply rapid responsiveness.

11.3 Historical Productivity

The coefficient

$$\mu(t)$$

measures the effectiveness of accumulated monetary history.

Large values indicate that previously accumulated resources strongly influence current dynamics.
Small values indicate limited historical influence.

12 Capital-Theoretic Interpretation

Suppose

$$M(t)$$

represents productive capital rather than money.

Then

$$H(t) = \int_0^t M(s)ds$$

measures cumulative capital deployment.

The identity

$$\lambda(t)\dot{M}(t) = \mu(t)H(t)$$

states that current capital expansion depends upon accumulated historical investment.
This interpretation is closely related to:

- capital-deepening models,
- learning-by-doing,
- cumulative innovation processes,
- endogenous-growth theory.

13 Finance

13.1 Recoverable Wealth Processes

Let

$$M(t)$$

represent portfolio wealth.
The recoverability condition

$$M(T) = M(0)$$

implies zero net change over the horizon.
Nevertheless,

$$\max_{0 \leq t \leq T} M(t) - \min_{0 \leq t \leq T} M(t)$$

may be substantial.
The process therefore separates

- terminal wealth,
- path-dependent wealth exposure.

13.2 Reserve Management

Central banks frequently experience temporary reserve accumulation followed by normalization.
The model provides a simple representation of such cycles.
The quantity

$$H(t)$$

can be interpreted as cumulative reserve commitment.

13.3 Volatility and Exposure

Even when

$$M(T) - M(0) = 0,$$

the memory variable

$$H(T) = \int_0^T M(s) ds$$

may be large.
Consequently, exposure and terminal outcomes need not coincide.

14 Political Economy

Political systems often generate temporary but substantial resource reallocations.
Examples include:

- election-related spending,
- industrial policy programs,
- infrastructure initiatives,
- emergency fiscal interventions.

Many such programs eventually terminate.
From the perspective of public finance,

$$M(T) = M(0)$$

may hold approximately even when large intermediate reallocations occur.

The harmonic-feedback structure provides a mechanism for diminishing influence across increasingly indirect policy channels.

14.1 Institutional Memory

Political institutions retain memory.

Past expenditures often affect future outcomes through:

- bureaucratic capacity,
- infrastructure networks,
- legal frameworks,
- public expectations.

The variable

$$H(t)$$

provides a stylized representation of such institutional memory.

15 International Relations

International systems frequently exhibit path dependence.

Examples include:

- alliance commitments,
- development assistance,
- diplomatic engagement,
- strategic investment.

Let

$$M(t)$$

denote resources committed to an international objective.

Then

$$H(t)$$

measures cumulative strategic commitment.

The coefficient

$$\mu(t)$$

captures the effectiveness of historical commitments in shaping present influence.

15.1 Strategic Persistence

Many geopolitical outcomes depend less on current expenditures than on cumulative historical commitments.

Examples include:

- alliance credibility,
- military interoperability,
- institutional integration,
- diplomatic reputation.

The memory formulation captures these persistent effects naturally.

16 Warfare Economics

Military systems are fundamentally path dependent.

Combat effectiveness depends not only on current resources but also on accumulated preparation.

Examples include:

- industrial mobilization,
- training programs,
- logistics networks,
- stockpile accumulation,
- research and development.

16.1 Military Memory

Let

$$M(t)$$

represent military expenditure.

Then

$$H(t) = \int_0^t M(s)ds$$

measures cumulative military commitment.

The resulting framework distinguishes between:

- current expenditure,
- accumulated military capacity.

16.2 Diminishing Strategic Feedback

Under harmonic feedback,

$$a_k = \frac{a_0}{1 + ka_0d},$$

higher-order feedback effects decline systematically.

This can be interpreted as diminishing marginal effectiveness of increasingly indirect strategic channels.

17 Comparative Interpretation

Quantity	Interpretation
$M(t)$	Current resources
$H(t)$	Historical commitment
$\lambda(t)$	Adjustment resistance
$\mu(t)$	Historical effectiveness
$Q_6(t)$	Feedback structure
d	Harmonic decay parameter
T	Recovery horizon

18 An Economic Principle

The framework suggests a general principle.

Systems may exhibit substantial historical dependence while remaining recoverable at finite horizons.

Recoverability therefore does not imply absence of memory.

Likewise, memory does not imply permanent divergence.

The coexistence of both properties constitutes the central idea of the theory developed in this paper.

19 Statistical Properties

The harmonic-feedback specification

$$a_k = \frac{a_0}{1 + ka_0d}$$

induces a structured decay across successive feedback orders.

Unlike arbitrary polynomial coefficients, the harmonic specification imposes a deterministic statistical regularity.

19.1 Monotonicity

Proposition 2. *Suppose*

$$a_0 > 0, \quad d > 0.$$

Then

$$a_0 > a_1 > a_2 > \dots > a_6 > 0.$$

Proof. Since

$$a_k = \frac{a_0}{1 + ka_0d},$$

the denominator increases strictly with k .

Therefore the sequence decreases strictly. □

19.2 Hyperbolic Decay

For sufficiently large k ,

$$a_k = \frac{a_0}{1 + ka_0d} \sim \frac{1}{kd}.$$

Thus harmonic feedback generates hyperbolic decay.

This differs from exponential decay,

$$a_k \propto e^{-\gamma k},$$

and geometric decay,

$$a_k \propto r^k.$$

Hyperbolic decay is commonly associated with long-memory systems.

20 Harmonic Decay Theory

Definition 3. *The harmonic decay ratio is defined by*

$$\rho_k = \frac{a_{k+1}}{a_k}.$$

Substituting the harmonic specification yields

$$\rho_k = \frac{1 + ka_0d}{1 + (k+1)a_0d}.$$

Hence

$$0 < \rho_k < 1$$

whenever

$$a_0 > 0, \quad d > 0.$$

Furthermore,

$$\lim_{k \rightarrow \infty} \rho_k = 1.$$

Thus the decay becomes progressively slower at higher orders.
This property is characteristic of long-memory structures.

21 Computer Science Interpretation

The recoverable-money framework may be interpreted as an abstract computational process.

Let

$$M(t)$$

denote the state of a computation.

Recoverability implies

$$M(T) = M(0),$$

meaning that the computation returns to its initial state after a finite horizon.

Examples include:

- reversible computation,
- cyclic state machines,
- periodic scheduling systems,
- bounded-memory algorithms.

21.1 State Compression

The memory variable

$$H(t) = \int_0^t M(s) ds$$

acts as a compressed representation of historical computation.

Rather than storing the complete trajectory, the system stores an aggregated memory statistic.

22 Artificial Intelligence and Machine Learning

The framework possesses natural analogues in machine learning.

22.1 Memory-Augmented Learning

Many learning systems maintain information about historical states.

Examples include:

- recurrent neural networks,
- long short-term memory networks,
- transformers with context windows,
- reinforcement learning agents.

The variable

$$H(t) = \int_0^t M(s) ds$$

may be interpreted as a continuous-memory state.

22.2 Credit Assignment

Learning systems often face a temporal credit-assignment problem.

The harmonic coefficients

$$a_k = \frac{a_0}{1 + ka_0d}$$

assign progressively smaller influence to increasingly indirect feedback pathways.

Consequently, harmonic feedback provides a natural mechanism for attenuating distant influences while preserving long-memory effects.

22.3 Model Complexity

The parameter

$$d$$

controls the rate at which higher-order influences diminish.

Large values of d imply aggressive attenuation.

Small values imply persistence of higher-order interactions.

23 Data Science Interpretation

In data science, memory variables frequently arise through cumulative transformations.

Examples include:

- cumulative returns,
- cumulative expenditures,
- cumulative user activity,
- cumulative engagement.

The quantity

$$H(t)$$

therefore represents a generic cumulative feature.

The harmonic kernel provides a structured method for weighting interactions among such features.

24 Algorithmic Construction

The recoverable-money process may be generated algorithmically.

24.1 Coefficient Construction

Given

$$m, \quad T, \quad a_0, \quad d,$$

compute

$$a_k = \frac{a_0}{1 + ka_0d}, \quad k = 0, \dots, 6.$$

Construct

$$Q_6(t) = \sum_{k=0}^6 a_k t^k.$$

Then define

$$M(t) = m + t(t - T)Q_6(t).$$

24.2 Pseudo-Code

```

INPUT:
m, T, a0, d

FOR k = 0,...,6
a[k] = a0/(1 + k*a0*d)
END FOR

Q = 0

FOR k = 0,...,6
Q = Q + a[k]*t^k
END FOR

M = m + t*(t-T)*Q

OUTPUT:
M

```

25 Numerical Illustration

Consider

$$m = 100,$$

$$T = 10,$$

$$a_0 = 1,$$

$$d = 1.$$

Then

$$a_k = \frac{1}{k+1}.$$

The resulting coefficients are shown below.

k	a_k
0	1
1	1/2
2	1/3
3	1/4
4	1/5
5	1/6
6	1/7

Consequently,

$$Q_6(t) = 1 + \frac{t}{2} + \frac{t^2}{3} + \frac{t^3}{4} + \frac{t^4}{5} + \frac{t^5}{6} + \frac{t^6}{7}.$$

The recoverable-money trajectory becomes

$$M(t) = 100 + t(t-10)Q_6(t).$$

By construction,

$$M(0) = 100,$$

and

$$M(10) = 100.$$

26 Generalizations

The framework admits numerous extensions.

26.1 Higher-Degree Feedback

One may replace

$$Q_6(t)$$

with

$$Q_n(t)$$

for arbitrary degree n .

The resulting recoverable process becomes

$$M(t) = m + t(t - T)Q_n(t).$$

26.2 Stochastic Recoverability

Introduce a stochastic disturbance

$$\varepsilon(t).$$

Then

$$M(t) = m + t(t - T)Q_n(t) + \varepsilon(t).$$

Such models may be useful in finance and macroeconomics.

26.3 Multi-Agent Systems

Suppose

$$M_i(t)$$

represents the resources of agent i .

The framework naturally extends to vector-valued systems.

Define

$$\mathbf{M}(t) = \begin{pmatrix} M_1(t) \\ \vdots \\ M_n(t) \end{pmatrix}.$$

Interactions among agents may then be introduced through coupled harmonic kernels.

26.4 Network Systems

A further extension replaces scalar feedback with matrix-valued feedback.

The resulting framework connects naturally with:

- network economics,
- financial contagion,
- alliance structures,
- supply-chain systems,
- distributed artificial intelligence.

27 Philosophical Interpretation

The theory highlights an important distinction between state and history.

Two systems may possess identical present states while having radically different histories.

The variable

$$M(t)$$

captures the current state.

The variable

$$H(t)$$

captures accumulated history.

Recoverability therefore does not erase memory.

Rather, it demonstrates that memory and return may coexist.

This observation extends beyond economics and applies broadly to social, political, strategic, and computational systems.

28 Conclusion

This paper developed a mathematical theory of recoverable money with sixth-degree harmonic feedback.

The principal results may be summarized as follows.

1. Every degree-eight recoverable monetary process admits the representation

$$M(t) = m + t(t - T)Q_6(t).$$

2. Harmonic feedback implies

$$a_k = \frac{a_0}{1 + ka_0d}.$$

3. The resulting feedback structure exhibits hyperbolic decay and long-memory behavior.
4. The framework admits interpretations in economics, finance, political economy, international relations, warfare economics, computer science, statistics, and artificial intelligence.
5. Recoverability and historical dependence are not mutually exclusive.

The resulting theory provides a flexible analytical framework for studying systems that temporarily depart from a benchmark state while ultimately returning to it.
