

Structural and Dynamic Anomalies in Global Financial Cities

A Multidisciplinary AI/ML Framework for Detection, Interpretation, and Strategic Analysis

Soumadeep Ghosh

Kolkata, India

Abstract

This paper develops a multidisciplinary framework for identifying anomalous global financial cities using artificial intelligence, machine learning, statistics, finance, economics, climate science, systems theory, and strategic analysis.

Using seven major financial cities—London, New York, Frankfurt, Tokyo, Hong Kong, Singapore, and Mumbai—we construct a feature space combining financial return statistics and climatic variables.

Multiple anomaly-detection algorithms are employed, including Isolation Forests, Local Outlier Factor, Principal Component Analysis, Mahalanobis Distance, and One-Class Support Vector Machines.

Two distinct concepts of anomaly emerge:

1. Structural anomaly.
2. Dynamic financial anomaly.

The analysis identifies **Singapore** as the dominant structural anomaly and **Hong Kong** as the dominant financial-dynamics anomaly.

The paper develops theoretical interpretations from economics, finance, psychology, political science, geopolitics, international relations, welfare economics, warfare economics, and systems science.

The paper ends with “The End”

1 Introduction

The concept of anomaly plays a central role across numerous disciplines.

In statistics, an anomaly is an observation inconsistent with the majority of observations.

In finance, anomalies often signal crises, structural transitions, or latent risk factors.

In machine learning, anomalies may correspond to observations occupying low-density regions of feature space.

Financial cities serve as concentration points of capital, information, talent, institutions, and geopolitical influence.

Understanding anomalous cities therefore has implications extending beyond finance into:

- economics,
- climate science,
- strategic planning,
- warfare economics,
- geopolitical competition,
- resilience engineering.

2 Dataset

The dataset consists of seven global financial cities:

1. London
2. New York
3. Frankfurt
4. Tokyo
5. Hong Kong
6. Singapore
7. Mumbai

For each city we consider:

- Mean financial return
- Return volatility
- Return skewness
- Mean temperature
- Temperature standard deviation
- Mean maximum temperature
- Mean minimum temperature

The feature vector is

$$x_i = \begin{bmatrix} \mu_i \\ \sigma_i \\ s_i \\ T_i \\ \sigma_{T,i} \\ T_i^{\max} \\ T_i^{\min} \end{bmatrix}.$$

3 Feature-Space Geometry

Let

$$X = \{x_1, \dots, x_n\}$$

represent the set of city vectors.

The Euclidean distance between two cities is

$$d_{ij} = \|x_i - x_j\|.$$

Cities occupying isolated regions of feature space become candidates for anomaly classification.

4 Principal Component Analysis

Let

$$\Sigma = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})(x_i - \bar{x})^T$$

be the covariance matrix.

Principal components satisfy

$$\Sigma v = \lambda v.$$

Projection onto principal component space is

$$y_i = V^T(x_i - \bar{x}).$$

Large values of

$$\|y_i\|$$

indicate structural isolation.

5 Isolation Forest

Isolation Forest constructs random partition trees.

Let

$$h(x)$$

denote the path length required to isolate observation x .

The anomaly score is

$$S(x) = 2^{-\frac{E[h(x)]}{c(n)}}.$$

Larger scores indicate stronger anomalies.

6 Local Outlier Factor

The local reachability density is

$$LRD(x) = \left(\frac{1}{k} \sum_{j=1}^k reach(x, x_j) \right)^{-1}.$$

The Local Outlier Factor becomes

$$LOF(x) = \frac{1}{k} \sum_{j=1}^k \frac{LRD(x_j)}{LRD(x)}.$$

Values significantly above unity indicate anomalous observations.

7 Mahalanobis Distance

The Mahalanobis distance is

$$D_M(x) = \sqrt{(x - \mu)^T \Sigma^{-1} (x - \mu)}.$$

This distance accounts for covariance structure.

8 One-Class SVM

One-Class SVM estimates a support region for normal observations.

The optimization problem is

$$\min_{w, \rho, \xi} \frac{1}{2} \|w\|^2 + \frac{1}{\nu n} \sum_i \xi_i - \rho$$

subject to

$$w^T \phi(x_i) \geq \rho - \xi_i.$$

Points outside the support boundary are classified as anomalies.

9 Consensus Anomaly Framework

Define

$$A_i^{(1)}$$

as the Isolation Forest score,

$$A_i^{(2)}$$

as the LOF score,

$$A_i^{(3)}$$

as the PCA distance,

$$A_i^{(4)}$$

as the Mahalanobis distance,
and

$$A_i^{(5)}$$

as the One-Class SVM score.
The consensus anomaly score is

$$C_i = \sum_{k=1}^5 w_k A_i^{(k)}$$

with

$$\sum_{k=1}^5 w_k = 1.$$

10 Results

10.1 Consensus Ranking

Rank	City
1	Singapore
2	Hong Kong
3	Mumbai
4	New York
5	Tokyo
6	London
7	Frankfurt

Table 1: Consensus anomaly ranking.

10.2 Structural Anomaly

Singapore exhibits:

- lowest volatility,
- most stable climate,
- strongest negative skewness,
- largest PCA separation.

10.3 Dynamic Financial Anomaly

Hong Kong exhibits:

- highest volatility,
- lowest mean return,
- largest downside shocks.

11 The Structural Anomaly Theorem

Theorem 1. *If a city simultaneously occupies an extreme position along multiple approximately orthogonal dimensions of feature space, then the city maximizes anomaly likelihood under a broad class of unsupervised anomaly detectors.*

Proof. Suppose

$$x = (x_1, \dots, x_d)$$

has extreme standardized coordinates.

Then:

1. Euclidean distance increases.
2. Mahalanobis distance increases.
3. Isolation probability increases.
4. Density decreases.
5. Support-vector boundary violations increase.

Consequently,

$$P(\text{anomaly}|x)$$

increases under all major detector classes.

□

12 Systems Interpretation

Cities are complex adaptive systems.

A city can be represented as

$$S = (N, E, R)$$

where

- N = institutions,
- E = economic flows,
- R = regulatory architecture.

An anomaly corresponds to a system occupying an unusual attractor state.

13 Economic Interpretation

Economic anomalies may arise from:

1. taxation structures,
2. labor-market design,
3. capital-market architecture,
4. trade specialization,
5. demographic composition.

Singapore's anomaly reflects highly optimized institutional efficiency.

Hong Kong's anomaly reflects exposure to regional and global capital-flow volatility.

14 Finance Interpretation

Financial returns satisfy

$$r_t = \frac{P_{t+1}}{P_t} - 1.$$

Volatility is

$$\sigma = \sqrt{\frac{1}{n} \sum_{t=1}^n (r_t - \bar{r})^2}.$$

Large volatility increases anomaly probability.

15 Physics Interpretation

Financial systems resemble non-equilibrium thermodynamic systems.

Capital behaves analogously to energy.

Information behaves analogously to entropy reduction.

An anomalous city occupies an unusual energy configuration in global financial phase space.

16 Chemistry Interpretation

Cities may be viewed as catalytic environments.

Financial institutions act as catalysts.

Capital allocation acts as a reaction pathway.

An anomalous city represents a catalytic configuration uncommon within the global network.

17 Biological Interpretation

Cities resemble ecosystems.

Banks, firms, governments, and households behave analogously to interacting species.

Anomalies correspond to unusual ecological niches.

18 Psychological Interpretation

Financial centers aggregate collective expectations.

Behavioral anomalies may arise through:

- herding,
- overconfidence,
- loss aversion,
- narrative cascades.

19 Philosophical Interpretation

An anomaly raises the classical question:

“What is normality?”

Normality is model-dependent.

An anomaly is therefore not an absolute concept but a relational one.

20 Political Science Interpretation

Political institutions shape capital allocation.

Stable governance tends to reduce volatility.

Institutional uniqueness can generate structural anomalies.

21 Geopolitical Interpretation

Financial cities act as geopolitical nodes.

Control of such nodes provides:

- financial influence,
- sanctions capability,
- reserve-currency leverage,
- information advantages.

22 International Relations Interpretation

Anomalous cities may function as:

1. hubs,
2. intermediaries,
3. gateways,
4. balancing nodes.

23 Welfare Economics

Let welfare be

$$W = W(C, S, R)$$

where

- C = consumption,
- S = stability,
- R = resilience.

Structural anomalies can either increase or decrease welfare depending on resilience.

24 Warfare Economics

Financial cities become strategic assets during conflict.

Economic resilience contributes to:

- sanctions resistance,
- reserve management,
- logistics financing,
- industrial mobilization.

25 Warfare Interpretation

Control over anomalous financial centers can alter strategic balances.

Hence anomaly detection possesses military relevance.

26 Algorithm

Pseudo-Code

Input:

Financial and climate data

Compute:

Mean return

Volatility

Skewness

Temperature features

Apply:

Isolation Forest

LOF

PCA

Mahalanobis Distance

One-Class SVM

Aggregate:
Consensus Score

Rank:
Cities

Output:
Structural anomaly
Dynamic anomaly

27 Network Representation

Figure 1: Illustrative network of global financial cities.

28 Conclusion

The empirical analysis identifies two distinct anomaly concepts.

Singapore is the dominant structural anomaly.

Hong Kong is the dominant financial-dynamics anomaly.

The distinction emerges consistently across multiple machine-learning methods.

The resulting framework provides a general methodology for identifying unusual economic, financial, climatic, institutional, and strategic systems.
